If you write your report in Overleaf	5

Requirements

Follow every item in this section. The rest of this guide is optional. If the current assignment disagrees with this guide, follow the assignment.

- The report file opens and includes your name, student ID, and assignment number.
- The report is written in English.
- The required source file (.qmd, .Rmd, .R, or .do) is included. **You must submit the source file this year.**
- Tables and figures are generated by code, not by screenshots of the Stata or R console.
- Numbers in the prose match the tables and figures.
- Every table and figure has a title.
- Tables and figures are self-contained: use descriptive labels, not the raw variable names from the data.
- Paths are relative, and the source runs from the beginning.

Overview

This guide is for students who are new to programming or empirical work. It explains how to use the starter kit, choose between R and Stata, check results before interpreting them, and prepare files for submission.

Choose R or Stata

You may use whichever software is easier for you. Python is also allowed. With any of these programs, the goal is to produce a clear report and source code that can regenerate the reported tables and figures.

The short starting points are the route folders next to this PDF. Copy one blank folder for your assignment. Each folder under `example/` is a finished sample in the same layout. Look at the sample, and do your own work in the copied folder.

Route	Use this when	Copy this folder and start here
R + Quarto	You want one document containing prose, code, tables, and figures	<code>r_quarto/</code> <code>report/replication_template.qmd</code>
R + R Markdown	You already use R Markdown	<code>r_markdown/</code> <code>report/replication_template.Rmd</code>
R + Overleaf	You analyze data in R and prefer to write the report in LaTeX	<code>r_overleaf/code/analysis.R</code> , then <code>r_overleaf/report/report.tex</code>
Stata + Overleaf	You have several tables or figures and prefer to write the report in Overleaf	<code>stata_overleaf/code/analysis.do</code> , then <code>stata_overleaf/report/report.tex</code>
Stata + putpdf	Overleaf is unavailable	<code>stata_putpdf/</code> <code>code/replication_template.do</code>

Filled samples, which you should not edit for your assignment:

- **R + Quarto.** `example/r_quarto/report/replication_template.qmd`
- **R + R Markdown.** `example/r_markdown/report/replication_template.Rmd`
- **R + Overleaf.** Run `example/r_overleaf/code/analysis.R`, then compile `example/r_overleaf/report/report.tex`.
- **Stata + Overleaf.** Run `example/stata_overleaf/code/analysis.do`, then compile `example/stata_overleaf/report/report.tex`.
- **Stata + putpdf.** `example/stata_putpdf/code/replication_template.do` writes `example/stata_putpdf/output/replication_report.pdf`.

The Overleaf examples first run the analysis script, which writes figures and tables into `output/`, and then compile the `.tex` file in `report/`. The Stata + putpdf example writes the PDF to `output/replication_report.pdf`.

Files and folders

Keep each assignment in one project folder. Avoid spaces and Japanese characters in file and folder names. Use relative paths for data, tables, and figures. Each blank route folder already uses this layout. Copy that folder and keep these four directories.

```
homework_01/
├─ data/      original data
├─ code/      R scripts or do-files
├─ output/    tables, figures, logs, and other outputs
└─ report/    qmd, Rmd, tex, and related files
```

Run scripts with this folder as the working directory. Paths in the filled examples are written from that root: `data/...` for inputs, `code/...` for scripts, and `output/...` for figures and tables. A Quarto or R Markdown file lives in `report/` and sets its working directory to the project root before it reads data.

Working in R

RStudio or Positron is the working environment; R is the programming language. Quarto or R Markdown combines prose and R code into a report. Create an RStudio Project for the copied route folder, open the template in `report/`, and render it once, without changing it, before you replace the placeholder text.

- Use an RStudio Project so that relative paths resolve from the assignment folder.
- Keep the analysis in a script or in the `.qmd` or `.Rmd` source file. Do not rely on commands typed only in the console.
- Install a package once, then load it with `library()` at the beginning of the source file.
- Before estimating a model, check the data with `glimpse()`, `summary()`, and `names()`, and count the number of observations.

```
library(tidyverse)
dat <- read_csv("data/data.csv", show_col_types = FALSE)
glimpse(dat)
summary(dat)
```

Working in Stata

Stata is available on the PCs at the OSIPP Network Center on the 3rd floor.

A do-file is the record of the analysis. Open the supplied do-file and run it from beginning to end. Replace the example commands only after that original example runs successfully. The commands `describe`, `codebook`, `summarize`, and `misstable summarize` are useful first checks.

```
clear all
set more off
use "data/data.dta", clear
describe
codebook
summarize
misstable summarize
```

The supplied do-files live in `code/`. If Stata's working directory is `code/` rather than the project root, those files move up to the project root before they read `data/` or write `output/`.

Check data, tables, and figures

- Keep the original data unchanged.

- Check variable types, missing values, duplicate observations, and the number of observations.
- Create tables and figures from code rather than copying output by hand.
- In tables and figures, use descriptive labels that explain what each variable represents instead of displaying raw variable names from the dataset. Include units where relevant.
- When needed, give figures informative titles, axis labels, units, legends, captions, and notes.

Interpret regression results

Do not stop at statistical significance. Explain the sign, magnitude, units, sample, and uncertainty. Use causal language only when the research design and its assumptions support a causal interpretation.

A one-unit increase in X is associated with a 0.08-unit increase in Y, holding the other covariates constant.

The phrase “is associated with” describes a conditional relationship. Replace it with a causal statement only when the assignment’s identification strategy supports that interpretation.

Common problems

Symptom	Common cause	First check
File not found	The working folder is different from what you expected	R: <code>getwd()</code> ; Stata: <code>pwd</code>
Variable not found	The name or spelling does not match the data	R: <code>names(df)</code> ; Stata: <code>describe</code>
Fewer observations than expected	Missing values or sample restrictions	R: <code>summary()</code> ; Stata: <code>misstable summarize</code>
A package or command is unavailable	It is not installed or is not on the search path	R: <code>library()</code> ; Stata: <code>which</code>
Old output appears	The source was not rerun	Run from the beginning and regenerate the output

When asking for help, include the software you use, the command or line that failed, the full error message, and a short description of what you expected. A screenshot alone usually does not identify the cause.

Choosing a reference

Choose a resource based on the software you use and the task you are working on. Use the assignment, course materials, and textbooks to check the required method and its econometric reasoning. The resources below are supplements for software and workflow questions.

If you use R

Resource	Who it is for	When to use it
R for Applied Economics	Students new to R or looking for a full workflow for an economics assignment	Follow its sequence from setting up R through data clean-

Resource	Who it is for	When to use it
Getting Started with R for Economists	Economics students who are new to R	ing, analysis, and presenting results. Learn R and RStudio, scripts and Projects, Quarto, data import and export, data wrangling, visualization, and statistical modeling.
R Markdown	Students using R Markdown	Find guidance on combining R code and prose in a reproducible report and on available output formats.
Quarto FAQ for R Markdown Users	Students who know R Markdown and are considering Quarto	Check how Quarto differs from R Markdown, how existing R Markdown documents are supported, and how to move to Quarto.
Quarto PDF Basics	Students producing PDFs with Quarto	Check PDF setup requirements and troubleshoot PDF rendering.

If you use Stata

Resource	Who it is for	When to use it
Applied Econometrics in Stata	Students new to Stata or programming	Work through tutorials on getting started with Stata, exploring and cleaning data, plotting, and randomized experiments and t-tests.
Producing Tables with estout	Students creating results tables in Stata	Use estout to export regression results and related output in tables.
Stata putpdf reference	Students creating a report PDF from Stata	Look up putpdf commands and syntax. This is the reference for the starter kit's stata_putpdf route.

If you write your report in Overleaf

Resource	Who it is for	When to use it
Overleaf account registration	Students using Overleaf for the first time	Create an account.

Resource	Who it is for	When to use it
Overleaf plans and pricing	Students starting with Overleaf's free plan	Check plan features and usage conditions. These may change, so check the current information on the linked page.
Overleaf: Learn LaTeX in 30 minutes	Students new to writing reports in LaTeX	Try the basic document structure, equations, tables, and other LaTeX features.

You do not need to read every reference as a command dictionary. Identify whether your current task is data import, cleaning, visualization, estimation, or reporting, then consult the resource that covers that task. If a reference gives an example that conflicts with the assignment, follow the assignment.
